

RETRACTABLE CAR COVER

BACKGROUND OF THE INVENTION

1. Field of the Invention

5 The present invention relates generally to a car cover stored in a canister that is deployed to cover a car, protecting the car from natural elements. More particularly, the present invention includes a novel cover that assists in facilitating deployment and storage of the cover.

10 2. Discussion of the Prior Art

Retractable car covers are known in the prior art. For example, U.S. Patent Number 4,856,842 to Ross et al., discloses a retractable car cover that is stored in a canister for selective deployment. The cover disclosed in the Ross reference is constructed from fabric commonly used in the art of car covers and is necessarily
15 significantly wider than the canister. As a result, as the cover is retracted into the canister, the canister must mechanically gather the sides of the cover. This may result in unwanted bunching of the cover that will in turn result in the cover becoming jammed within the canister.

Other references, such as U.S. Patent Number 6,131,643 to Cheng et al., disclose
20 alternative retractable car covers. The cover of the Cheng reference includes side panels that are folded over a middle panel for preparing the cover for storage. The folded cover is then reeled in and stored about a drum located in the trunk of the car. During retraction, the user must insure that the side panels remain flat against the middle panel to prevent unwanted bunching of the cover. As the cover in the Cheng reference is
25 configured to be stored in the trunk of a car, deployment and retraction of the cover requires the trunk of the car to be opened. In addition, the cover only covers the cabin and forward hood areas of the car, leaving the trunk area unprotected.

There is a need in the art of retractable car covers to provide a cover incorporates many of the benefits of the prior art car covers while addresses the concerns noted above. The present invention addresses these concerns.

5 BRIEF SUMMARY OF THE INVENTION

10 A retractable vehicle cover apparatus for selectively covering a vehicle broadly comprises an elongated, hollow housing, and axle disposed within the housing for rotational movement about a central axis, and an elongated, expandable cover having a first, distal end and a second, proximal end coupled with the axle. The housing includes side wall structure having an elongated aperture presenting a length defined through the wall structure. The proximal end of the cover is fed through the aperture so that the cover may be selectively moved between a retracted position where the cover is wrapped around the axle, and an extended position where a substantial portion of the cover extends from the housing.

15 The cover includes several layers to yield a cover configured to protect the vehicle from the elements, inhibit scratching or other signs of wear on the vehicle during usage, and permit selective expansion of the cover in order to more fully cover the vehicle. More particularly, the preferred cover includes an outer, generally opaque, water resilient layer, a middle, elastic layer and an inner layer of protective padding. The elastic layer biases the cover toward a rest width substantially the same as the length of the aperture to facilitate extension and retraction of the cover to and from the housing, while permitting selective expansion of the cover. A pair of straps are attached to the side edges of the cover and may be selectively coupled to the lower portion of the sides of the vehicle in order to maintain the cover in the expanded condition.

25 The housing includes coupling structure for removably coupling the housing to a vehicle. The coupling structure includes a pair of support arms attached to the housing side wall structure and a support bracket configured to be mounted directly on the frame of the vehicle.

A cover extension and retraction system is located in the housing. The system

includes a ratchet wheel mounted on the axle and a pawl engaging the wheel permitting rotation of the wheel, and thus the axle in a first, counter-clockwise direction for extension of the cover. A release button is used to selectively disengage the pawl from the ratchet wheel to permit rotation of the wheel in a second, clockwise direction to permit retraction of the cover into the housing. A crank handle is coupled with the axle for facilitating rotation of the axle.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

A preferred embodiment of a retractable car cover is described in detail below with reference to the drawing figures, wherein:

Figure 1a is a perspective view of a car with a retractable car cover apparatus constructed in accordance with a preferred embodiment of the present invention coupled to the rear of the car;

Fig. 1b is a perspective view showing more detail of the attachment structure of the preferred apparatus;

Fig. 1c is a perspective view of the car cover extended over the length of the car;

Fig. 2a is a side elevation of the car cover in a deployed configuration;

Fig. 2b is a perspective view of the car cover in the deployed configuration;

Fig. 2c is a perspective view showing more detail of the straps used for maintaining the cover in the deployed configuration;

Fig. 3a is an exploded view of the ratchet and pawl retraction system for the cover;

Fig. 3b is a perspective view of the housing with the cap removed showing the ratchet and pawl retraction system;

Fig. 4 is an exploded view of various components of the apparatus;

Fig. 5a is a cross-sectional view of the car cover of the present invention in a rest state;

Fig. 5b is a cross-sectional view of the car cover of the present invention in an expanded state;

Fig. 6a is a partially exploded view of a retractable car cover the apparatus

constructed in accordance with a preferred embodiment of the present invention;

Fig. 6b is a perspective view of a retractable car cover apparatus constructed in accordance with an alternative embodiment of the present invention;

Fig. 7a is a perspective view of an alternative car cover extended over a car; and

5 Fig. 7b is a perspective view of the car cover of Fig. 7a in an expanded configuration, covering the car.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

Referring now to the drawings, Figure 1a depicts a retractable vehicle cover apparatus 10 constructed in accordance with a preferred embodiment of the present invention coupled to the frame of a car 12. The cover apparatus 10 broadly comprises an elongated, generally cylindrical housing 14 having side wall structure defining an interior cavity, and a cover 16 received in the cavity of the housing 14 for selective retraction and extension to and from the housing 14. The cover 16 includes a distal first end 18 and a proximal second end 20. The cover 16 is expandable to more fully cover the car 12, as shown in Figs. 2a, 2b.

Fig. 4 depicts additional detail concerning some of the elements of the apparatus 10. An axle 22 is disposed within the cavity of the housing 14 for rotational movement about a central axis. The proximal end 20 of the cover 16 is coupled with the axle 22. The housing 14 includes side wall structure having an elongated aperture 24 presenting a length defined through the wall structure. The proximal end 18 of the cover 16 is fed through the aperture 24 so that the cover 16 may be selectively moved between a retracted position (shown in Fig. 1a) where the cover 16 is substantially wrapped around the axle 22, and an extended position (shown in Fig. 1c) where a substantial portion of the cover 16 extends from the housing 14. A pair of drain holes 25 are also formed in the wall structure for facilitating drainage of unwanted water accumulated during inclement weather.

The housing 14 includes coupling structure for removably coupling the housing 14 to the frame of the car 12. As shown in Fig. 4, the coupling structure includes a pair of support arms 26 attached to the housing side wall structure and a support bracket 28 configured to be mounted directly on the frame of the car 12. The support arms 26 each include a base 30 and a hanger 32. The hangers 32 have a plurality of positioning apertures 34 defined therethrough. The support bracket 28 includes a pair of depending sleeves 36 sized for telescopically receiving the hangers 28. The sleeves 36 have a plurality of sleeve apertures 38 defined through the sleeves 36.

The housing 14 is mounted on the car 12 by inserting the hangers 32 into the corresponding sleeve 36, and adjusting the hanger therein until the housing 14 is located in a desired position beneath the car 12 and one set of the positioning apertures 34 is aligned with one set of the sleeve apertures 38. A locking pin 40 (shown in Fig. 1b) is then inserted through each set of aligned positioning and sleeve apertures 34, 38. For security, a pad lock 42 is coupled with the pin 40, securely fixing the apparatus 10 to the car 12.

Turning now to Figs. 3a and 3b, a cover extension and retraction system 44 is located in the housing 14 for selectively extending the cover 16 toward the extended position, and retracting the cover 16 toward the retracted position. The system 44 includes a ratchet wheel 46 having a plurality of radially disposed teeth 48 mounted on the axle 22 and a pawl 50. The pawl 50 includes a pawl bracket 52 and a pawl arm 54 pivotally mounted on the bracket 52. The pawl arm 54 is biased toward an engagement position engaging the teeth 48 of the wheel 46 permitting rotation of the wheel 46, and thus the axle 22 in a first, counter-clockwise direction for extension of the cover 16. A release button 56 is positioned for linear movement between an upper position and a lower, pawl releasing position. A spring 58 biases the button 56 toward the upper position.

A crank handle 60 is coupled with the axle 22 for effecting the desired rotation of the axle 22. To retract the cover 16, the release button 56 is depressed toward the release position, so that the pawl arm 54 pivots and disengages from the teeth 48 of the wheel 46.

The crank handle 60 is then used to rotate the axle 22 in a clockwise direction, retracting the cover 16 into the housing 14. A pair of end caps 62, 64 are provided for containing the various interior elements of the housing 14.

The housing 14 further includes a pair of opposed rollers 66, 68 mounted on the exterior of the housing 14 and positioned adjacent to the aperture 24 (Figs. 3b and 4). The rollers 66, 68 assist in evenly wrapping the cover 16 about the axle 22 and inhibiting unwanted bunching of the cover 16 during retraction, a condition that could lead to accidental jamming of the apparatus 10.

A cross-sectional view of the preferred cover 16 is shown in Figs. 5a, 5b. The cover 16 includes several layers configured to protect the car 12 from the elements, inhibit scratching or other signs of wear on the car during usage of the apparatus 10, and permit selective expansion of the cover 16 in order to more fully cover the car 12.

5 More particularly, the cover 16 includes an outer, generally opaque, water resilient layer formed from a plurality of flexible, aligned cover strips 70, a middle, elastic layer 72 and an inner layer formed from a plurality of aligned padded strips 74. Preferably, the cover strips 70 are constructed from a generally flexible, opaque, synthetic resin material. The cover strips 70 are mated to the elastic layer 72. The elastic layer 72 biases the cover
10 16 toward a rest condition in which the width of the cover 16 is substantially the same as the length of the aperture 24 in the housing 14. As a result, the width of the cover 16 facilitates extension and retraction of the cover 16 to and from the housing 14.

When the cover 16 is in the rest condition, the cover strips 70 overlap one another, as shown in Fig. 5a, permitting the cover 16 to narrow. In this condition, the padding
15 strips 74 abut each other. When the cover 16 is expanded toward the expanded condition for covering the car 12, the cover strips 70 move into a position tending to abut each other, as shown in Fig. 5b. This yields a generally water resilient, opaque outer layer. The padding strips 74 are spaced apart when the cover 16 is in the expanded condition and function as a protective layer between the surface of the car 12 and the middle and
20 outer layers of the cover 16.

Cover attachment structure is coupled with the proximal end 18 of the cover 16. The attachment structure includes an end rail 76 and a pair of hooks 78 (Fig. 3b). The end rail 76 functions to prevent the proximal end 18 of the cover 16 from being entirely withdrawn into the housing 14 and to provide a gripping surface for a user of the
25 apparatus 10 to pull the proximal end 18 and extend the cover 16 toward the extended position. Alternatively, a bolt rope (not shown) may be coupled to the proximal end 18 of the cover 16. A bolt rope would be less likely to scratch or otherwise damage the car 12 during usage of the apparatus 10.

When the cover 16 is extended over the car 12, the hooks 78 are positioned to

secure the proximal end 18 of the cover 16 to the car 12. The handle 60 is then rotated clockwise to provide slight tension on the cover 16, further securing the hook 78 and thus the cover 16 to the car 12.

5 A flexible rail, cable or bolt rope is provided along the opposed side edges 80 of the cover 16. A pair of straps 82 are attached to each of the side edges 80 of the cover 16 and are selectively coupled to the lower rocker panel of the car 12 in order to maintain the cover 16 in the expanded condition (Fig. 2c). The rails act to spread the tensile force of the straps 82 along the edges 80 of the cover.

10 In use, the support bracket 28 is secured to the frame of the car 12. The housing 14 is then positioned at the rear of the car 12 by inserting the hangers 32 into the corresponding sleeves 38. After the corresponding positioning apertures 34 are aligned with the desired sleeve apertures 38, the locking pins 40 are inserted through the aligned apertures 34, 38. At least one of the locking pins 40 is secured in place by the pad lock 42. The car 12 may be operated in an unimpeded manner with the apparatus 10 in
15 position for usage.

The proximal end 18 of the cover 16 is then pulled from the housing 14, over the top of the car 12 until the hooks 78 are coupled with the front of the car 12. The release button 56 is depressed and the handle 60 is rotated clockwise until sufficient tension is placed on the cover 16 to secure the hooks 78 to the front of the car 12. Releasing the
20 button 56 re-engages the pawl 50 with the ratchet wheel 46, locking the cover 16 in place.

The straps 82 are then pulled and attached to the lower rocker panels along the sides of the car 12. When the straps 82 are in position, the cover 16 will have been stretched into the expanded condition, covering a substantial portion of the car 12.

25 The car 12 is uncovered by detaching the straps 82 from the rocker panels, permitting the elastic layer 72 to return the cover 16 to its rest width. In the rest width, the cover 16 may be retracted into the housing 14 through the housing aperture 24. This is accomplished by depressing the release button 56 disengaging the pawl 50 from the ratchet wheel 46 and rotating the handle 60 clockwise, retracting the cover 16 until a desired amount of the cover 16 is withdrawn into the housing 14. The apparatus 10 may

be left in place for future use, or removed and placed into storage.

As shown in Figs. 6a and 6b, a handle 84 may also be mounted on the end rail 76. The handle 84 facilitates gripping of the proximal end 18 of the cover 16 for extension of the cover 16 toward the extended position.

5 During retraction of the cover 16, the straps 82 are positioned to rest on the upper, protective layer, so that as the cover 16 is retracted, the straps 82 are rolled up in the cover 16. Alternatively, hook and loop material may be used to secure the straps 82 to the cover 16 for retraction of the cover 16.

10 An alternative extension and retraction system is shown in Fig. 6b. The alternative system utilizes an electrically driven motor 85 for retraction of the cover 16. The motor 85 is electrically coupled with an electrical source (not shown).

15 An elongated, alternative cover 86 is depicted in Figs. 7a and 7b. The alternative cover 86 includes a distal end 88 and a proximal end 90 coupled with the axle 22. The cover 86 further includes an outer protective layer 92 and several elastic bands 94 underneath the protective layer 92. The bands 94 bias the cover 86 toward a rest width substantially the same as the length of the aperture 24, permitting extension and retraction of the cover from and to the housing 14. The bands 94 permit the cover 86 toward an expanded condition wherein the cover 86 is capable of covering a large portion of the car 12. A pair of straps 96 are coupled to the side edges 98 of the cover 86 for holding the
20 cover 86 in the expanded condition while covering the car 12. The alternative cover 86 is extended and retracted in much the same manner as the preferred cover 16.

The invention has been described in the above preferred embodiments with reference to the drawing figures. It is understood that substitutions may be made and equivalents employed herein without departing from the scope of the invention as set
25 forth in the following claims.
